5.1

We have $M = (Q, \Sigma, \delta)$ and $\pi = \{H_i\}_{i \in I}$ a admissible partition of Q . If M is complete then for all $i \in I$ and for all $a \in \Sigma$ there exists **exactly one** partition such that for $j \in I$ $H_i \delta_a \subseteq H_j$. By definition of π (Lemma 3.48) there exists **at least one** $j \in I$ with $H_i \delta_a \subseteq H_j$. Notice $H_i \delta_a \neq \emptyset$ because M is complete.

We show that there only exists **exactly one** $j \in I$. Suppose there exists $j, k \in I$ with $H_i \delta_a \subseteq H_{j,k}$ for all $a \in \Sigma$ and $j \neq k$. We choose an arbitrary $q \in H_i$ then the following must hold:

$$q\delta_a = q_j \in H_j$$

$$q\delta_a = q_k \in H_k$$

Notice $q_j \neq q_k$ because $H_j \cap H_k = \emptyset$. This is a contraction because $q\delta_a$ is not right unique anymore.

5.2

We prove for a transformation semigroup transformation (Q, S) which is irreducible such that for all $q \in Q$ either $|qS| = 1$ or $qS = Q$. Assume $|qS| = 1$ for a given $q \in Q$. This means we find one arbitrary but fixed $q' \in Q$ such that $qS = q'$. Moreover, $q = H_i$ and $q' = H_j$ with $i, j \in I$, it is the trivial partition of singleton classes. Now assume $qS = Q$ for a given $q \in Q$. This means for each $s \in S$ with $qs = q'$ we map to a different q' such that $\bigcup q' = Q$. Thus, we get the trivial partition of Q .

Finally suppose $|qS| > 1 \wedge qS \neq Q$ for any $q \in Q$. Then there exists $qs' = q'$ and $qs'' = q''$ with $q' \in H_j, q'' \in H_k$ and $j \neq k$. Also notice that that there exists at least one other $s''' \in S$ which is also in H_j or H_k because otherwise $qS = Q$. k Therefore

5.3

1. Since, $\text{Aut}(M)$ is the set of all state machine automorphisms, this means that f is a bijective function on $Q \times Q$, therefore, it only permutes the states of M . As, Σ

is mapped to Σ by the identity function, the transactions δ of M do not change. Given Lemma 2.89, we know that given a set Q , (S_Q, \circ, id_Q) is a group. We have already established that $Aut(M)$ only permutes states of M , and as $Aut(M)$ includes 'all' state machine automorphisms, it also includes the identity function. This concludes the proof, that $Aut(M)$ is a group. \square

2. Let $q_1, q_2 \in Q$ arbitrary but fixed with $q_1 = q_2 \delta_w$ with $w \in \Sigma^*$ and $q_1 \neq q_2$. Let's assume, that $f(q_1) = q_1$. Since, $Aut(M)$ is a state machine homomorphism with (f, id_Σ) ,

$$f(q \delta_w) \subseteq (f(q)) \delta'_{id(w)} \quad (5.1)$$

holds true. For q_1, q_2 and w this results in:

$$f(q_1) = (f(q_2)) \delta_w \quad (5.2)$$

$$q_1 = q'_2 \delta_w | q_2 \in Q \quad (5.3)$$

For (5.3) to be true, q'_2 would have to equal q_2 , since δ and Σ have not changed. This, however, would mean that if $f(q_1) = q_1 \rightarrow \forall q \in Q : f(q) = q$, since there exists a $w \in \Sigma^*$ for all $q_1, q_2 \in Q$ with $q_1 = q_2 \delta_w$, since, M is transitive.
